

# Multi-phase pressure diffusion

In majority of practical well tests the [pressure diffusion](#) in multi-phase segregation of reservoir flow the pressure response can be approximated by [single-phase pressure diffusion model](#) with a specific from of fluid/reservoir properties.

This approximation can be done in one of three ways:

Linear Perrine multi-phase diffusion	the simplest <a href="#">multi-phase fluid</a> model although it has a 3-phase form it normally works for oil-water system only
Pseudo-linear multi-phase diffusion	this model is capable to account for highly compressible <a href="#">multi-phase fluid</a> components (light oil, condensate and gas) and <ul style="list-style-type: none"><li>• in case of high drawdown it does not model pressure accurately both in near and far reservoir zone</li><li>• requires analyst to select a reference pressure point where the pressure simulation will be more accurate</li></ul>
Non-linear multi-phase diffusion	this <a href="#">multi-phase fluid</a> model covers a wide range of <a href="#">2-phase</a> and <a href="#">3-phase</a> models in a wide range of pressure variations and <ul style="list-style-type: none"><li>• it does not account for capillary pressure</li><li>• it does not cover the segregated gas-liquid reservoir flow</li></ul>
