

Pressure spatial superposition principle @ model

Implication that pressure $p(t, \mathbf{r})$ at any point $\mathbf{r}$ of a **porous reservoir** is a linear sum of pressure responses $\delta p_k(t, \mathbf{r})$ to individual rate variations $q_k(t)$ in all wells connected to this reservoir:

$$(1) \quad p(t, \mathbf{r}) = p_i + \sum_k \delta p_k(t, \mathbf{r}) = p_i + \sum_k \int_0^t p_{uk}(t - \tau, \mathbf{r}) dq_k(\tau)$$

In case reservoir point $\mathbf{r}$ defines location of m -well the **superposition principle** can be rewritten as:

$$(2) \quad p_m(t) = p_{mi} + \sum_k \delta p_{mk}(t) = p_{mi} + \sum_k \int_0^t p_{umk}(t - \tau) dq_k(\tau) = p_{mi} + \int_0^t p_{umm}(t - \tau) dq_m(\tau) + \sum_{k \neq m} \int_0^t p_{umk}(t - \tau) dq_k(\tau)$$

where

p_{mi}	initial formation pressure in m -well
$\delta p_{mk}(t)$	specific component of m -well pressure variation caused by k -well flowrate history $q_k(t)$
$p_{umm}(\tau)$	bottomhole pressure response in m -well to unit-rate production in the same well (DTR)
$p_{umk}(\tau)$	bottomhole pressure in m -well to unit-rate production in k -well (CTR), $k \neq m$
