

Subsurface Temperature Profile around Lateral Flow Analytical @model

Motivation

[Subsurface Temperature Profile around Lateral Flow](#) makes adjustments to [Geothermal Temperature Profile](#) $T_G(z)$ to account for the lateral reservoir flow with a constant temperature (see [Fig. 1](#) and [Fig. 2](#)).

Outputs

$T_e(t, z)$ Subsurface temperature distribution

Inputs

t	Time lapse after the temperature step from $T_e(z = 0) = 0$ up to $T_e(z = 0) = T_f$
z	Spatial coordinate along the transversal direction to constant temperature $T_e(z) = T_f$ plane $z = 0$
z_f	TVDss of the top of the lateral flow unit
h_f	True vertical thickness of the the lateral flow unit

T_f	Boundary temperature at $z = 0$
a_e	Thermal diffusivity of the surroundings
$T_G(z)$	Geothermal Temperature Profile

Equations

Driving equation	Initial conditions	Boundary conditions
(1) $\frac{\partial T_e}{\partial t} = a_e^2 \Delta T_e = a_e^2 \frac{\partial^2 T_e}{\partial z^2}$	(2) $T_e(t = 0, z) = T_G(z)$	(3) $T_e(t, z_f \leq z \leq z_f + h_f) = T_f = \text{const}$ (4) $T_e(t, z \rightarrow \infty) = T_G(z)$

Solution

(5) if $z < z_f \implies T_e(t, z) = T_f + (T_G(z) - T_f) \cdot \text{erf}\left(\frac{z_f - z}{\sqrt{4a_e t}}\right)$
(6) if $z_f \leq z \leq z_f + h_f \implies T_e(t, z) = T_f$
(7) if $z > z_f + h_f \implies T_e(t, z) = T_f + (T_G(z) - T_f) \cdot \text{erf}\left(\frac{z - z_f - h_f}{\sqrt{4a_e t}}\right)$

where

erf(x) Error function
