Pump @model

The most general Pump model is given as a function of the mass flowrate on the intake p_{in} and discharge pressure p_{out}:

(1) $$\dot{m} = M(p_{\text{out}}, p_{\text{in}})$$

It's often presented in terms of intake volumetric flowrate:

(2) $$q = q_{in} = \frac{\dot{m}}{\rho(p_{in})} = \frac{M(p_{\text{out}}, p_{\text{in}})}{\rho(p_{in})}$$

where

$\rho(p)$	fluid density as a function of fluid pressure p

The electrical power consumption $W = \frac{dE}{dt}$ is given by:

(3) $$W = \eta(q) \cdot q \cdot (p_{\text{out}} - p_{\text{in}})$$

where

η	pump efficiency

In most practical cases the pump model (2) depends on the difference between intake and discharge pressure $p_{\text{out}} - p_{\text{in}}$ and called Pump Characteristic Curve (see **Fig. 1**):

(4) $$q = q(p_{\text{out}} - p_{\text{in}})$$

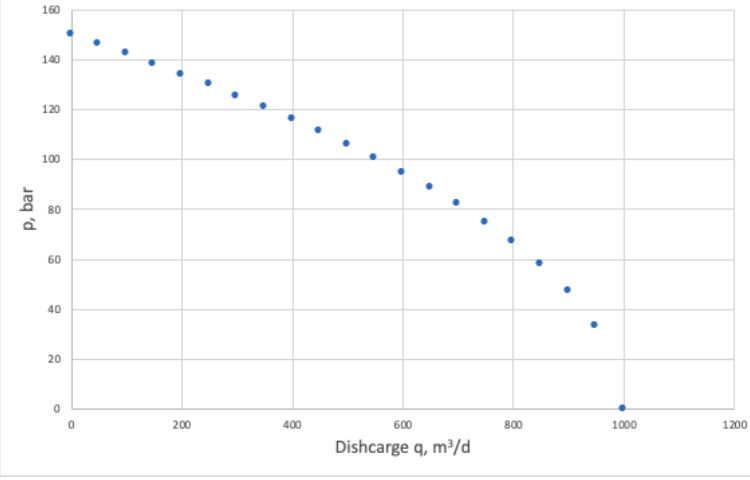

Fig. 1. Example of Pump Characteristic Curve.

A popular pump proxy model is given by the quadratic equation with 3 inputs ($\{q_{rfmax}, \delta p_{\max}, k_f\}$):

(5) $$q = \frac{q_{\max}}{2 \cdot k_f} \cdot \left[-1 + k_f + \sqrt{(1+k_f)^2 - 4 \cdot k_f \cdot (p_{\text{out}} - p_{\text{in}})/\delta p_{\max}}\right]$$

(6) $$p_{\text{out}} = p_{\text{in}} + \delta p_{\max} \cdot \left[1 + (k_f - 1) \cdot \frac{q}{q_{\max}} - k_f \cdot \left(\frac{q}{q_{\max}}\right.\right.$$

(7) $$\eta(q) = 4\,\eta_{\max} \cdot q/q_{\max} \cdot (1 - q/q_{\max})$$

where

$\delta p_{\max}$	maximum pressure gain that pump can exert over the input pressure p_{in}
$q_{\max}$	maximum flowrate that pump can produce
$k_f \in [0, 1]$	total hydraulic pump friction (dimensionless)
η	pump efficiency
$\eta_{\max}$	maximum pump efficiency

Real pumps have non-constant $k_f = k_f(q)$ friction coefficient which often modelled as a 3rd order polynomial and the overall real-pump model taking 6-inputs.

Many pumps can be normally adjusted by the variation of the working frequency which affects the maximum pump flowrate and maximum pressure gain as:

(8) $q_{\max} = q^*_{\max} \cdot \frac{f}{f^*}$	(9) $\delta p_{\max} = \delta p^*_{\max} \cdot \left(\frac{f}{f^*}\right)^2$

where

$q_{\max}$	maximum intake flowrate at the working frequency f	$\delta p_{\max}$	maximum pressure gain at the working frequency f	f	adjusted working frequency
$q^*_{\max}$	maximum intake flowrate at the nominal frequency f^*	$\delta p^*_{\max}$	maximum pressure gain at the nominal frequency f^*	f^*	nominal frequency
