

Oil Control (Reservoir Flow Modelling)

Specification of DFM dynamic inputs and outputs at well level:

Dynamic Input	Dynamic Output
<ul style="list-style-type: none">• Oil rate	<ul style="list-style-type: none">• BHP• Formation pressure• Water cut• GOR

The [Oil Control](#) is a misnomer as it does not correspond to any physical [Lift Mechanism](#) and in fact represents a mathematical technique to adjust simulated [bottomhole pressure](#) history to match historical [oil production](#) in each well.

It is not encouraged for practical applications.

Most reasonable use of [Oil Control](#) is to perform primary model runs to calibrate reservoir volume and oil-in-place.

Once completed the [history matching](#) should be continued in [Liquid Control](#) or [Pressure Control](#) mode to replicate the actual [Well Control](#).
